I'm running a Linux server with a limited amount of memory. I have a Java application running that should be able to create an infinite amount of objects (unknown number). The objects take up nearly 100% of the available heap space. The garbage collector kicks in when there is about 20mb free. I run "java -XX:+UseGCOverheadLimit" and the GC works fine. The memory is freed

---

when the GC runs, and the allocated memory gets free. The problem is that when the GC runs, the server's response time is extremely slow and other applications on the server have an extremely hard time to get it's allotted memory back. The OS becomes overloaded with various requests and the memory is never returned to the other applications. I can manually set the heap size for the applications and this works fine, but the problem is that I have no idea how to set the memory when running in production. The Question Is there any way I can tell the GC to not run the collector so I can increase the heap size? Is there any way I can tell the GC to allocate more memory before it starts running? A: I can only assume that you have no control over the amount of memory available to the JVM as a whole. In this case, I would suggest setting up some automated script to start up the JVM with a new heap size, wait a while, and then restart it. I would do this and check the results. You could also try running the JVM with `JAVA_OPTS="-Xmx256M 82157476af`
